Recourse and Residential Mortgage Default: Evidence from U.S. States*

Andra C. Ghent and Marianna Kudlyak†

Federal Reserve Bank of Richmond Working Paper No. 09-10R

February 25, 2011

Abstract

We quantify the effect of recourse on default. We find that recourse affects default through lowering the borrower's sensitivity to negative equity. At the mean value of the default option for defaulted loans, borrowers are 30% more likely to default in non-recourse states; for homes appraised at $500,000 to $750,000, borrowers are twice as likely to default in non-recourse states. We also find that, in states that allow deficiency judgments, defaults are more likely to occur through a lender-friendly procedure, such as a deed in lieu. We find no evidence that mortgage interest rates are lower in recourse states.

1 Introduction

The common view is that U.S. mortgages are non-recourse, either by law or in practice. Feldstein (2008), for example, asserts that "mortgages are generally 'no recourse' loans" and suggests that the reason Europe has much lower default rates is because mortgages in Europe are recourse. Those who do recognize that recourse is available in some states still do not attribute a significant role to recourse in the borrower's default decision. For example, Karl E. Case points out that recourse is rarely done: "It's tough to do recourse. It's costly, and the amount of people's non-housing wealth tends to be pretty slim" (Leland [2008]). A popular real estate textbook states that "[t]he value of deficiency judgments is always open to serious question. This is true in part because of the ways by which they can be avoided or defeated" (Brueggeman and Fisher [2011]). The existing evidence seems to support this view: deficiency judgments are rarely observed.

We show that the above viewpoint is false. First, in many U.S. states, residential mortgages are recourse. In recourse states, the lender may be able to collect on debt not covered by the proceedings from a foreclosure sale by obtaining a deficiency judgment. Second, the effect of recourse is not reflected in the frequency of deficiency judgments but, instead, in the way the threat of recourse alters borrower behavior.

We use loan-level data to empirically investigate the importance of recourse for default behavior. We find that recourse decreases borrowers' sensitivity to negative equity, i.e., recourse deters some borrowers with negative equity from defaulting. The effect is substantial: on average, the monthly probability of default is 1.32 times higher if there is no threat of recourse then if the loan is recourse, as measured at the average value of negative equity for defaulted loans. *Ceteris paribus*, it takes 8.6% more negative equity to make the probability of default in a recourse situation the same as the probability of default in a non-recourse situation.

Importantly, recourse affects default only through lowering borrowers' sensitivity to negative equity. Unconditionally, there is no difference between the default rates in recourse and non-recourse states. Furthermore, even controlling for loan and borrower characteristics, including only a dummy for whether the state is recourse or non-recourse in levels, we find

that recourse does not have a statistically significant effect on the default rate. We find that recourse has a significant effect on default only when we interact recourse with the default option value.

However, there are situations in which recourse does not affect borrower behavior. The effect of recourse is significant only for higher-appraised properties. In particular, we find that, for properties appraised at less than $200,000 (at origination, in real 2005 terms), there is no difference in the probability of default across recourse and non-recourse states. Conversely, at the mean value of the default option at the time of default and for homes appraised at $500,000 to $750,000, borrowers in non-recourse states are more than twice as likely to default as borrowers in recourse states.

We also find that allowing the lender recourse increases the likelihood that default occurs by a more lender-friendly method, such as a deed in lieu of foreclosure. This result is likely because lenders in recourse states have better bargaining positions. Furthermore, we find that a larger fraction of defaults in non-recourse states are likely to be strategic insofar as borrowers who default in non-recourse states are less likely to resume payments following the delinquency that precedes the foreclosure.

We also investigate differences in mortgage rates between recourse and non-recourse states. To the extent that borrowers in recourse states are less likely to default in response to negative equity, and are more likely to default in a lender-friendly way if they do default, lenders are likely to face smaller losses from default in recourse states. Thus, one might expect interest rates to be lower in recourse states. However, we find no evidence that they are; in fact, we find that loans are more expensive in recourse states. This is a surprising result that needs further investigation.

Our finding that recourse deters some borrowers from defaulting indicates that a non-negligible portion of U.S. mortgage default is in fact strategic rather than involuntary, i.e., when borrowers have no choice but to default because of liquidity constraints. This finding contrasts with the view that mortgage defaults are primarily driven by shocks to the borrower's ability to pay. For example, based on their analysis of a rich dataset from Massachusetts, Foote, Gerardi, and Willen (2008) conclude that negative equity is not a sufficient condition for default. However, Massachusetts is a recourse state, and analyzing data only

from recourse states gives an incomplete picture of the role of negative equity in the borrower's default decision. As our findings show, the borrower's decision to default in recourse states is substantially less sensitive to negative equity than in non-recourse states. Guiso, Sapienza, and Zingales (2009) and Bhutta, Dokko, and Shan (2010) also find that at least some portion of default is not due to liquidity constraints.

Earlier work by Clauretie (1987), Jones (1993), and Ambrose, Capone, and Deng (2001) has also looked empirically at differences in defaults across jurisdictions.[1] Clauretie (1987) estimates a linear regression model of aggregate state default rates and finds that whether or not a state permits a deficiency judgment does not significantly affect the state's default rate. Jones (1993) looks at evidence from Alberta, which does not permit deficiency judgments, and British Columbia, which does permit them, and finds that defaults in Alberta are more likely to be deliberate, rather than caused by trigger events in the borrower's life. Ambrose, Capone, and Deng (2001) include a dummy variable for whether a state allows a deficiency judgment in their study of the determinants of mortgage default in a sample of Federal Housing Administration (FHA) loans originated in 1989. Because the principal of FHA loans is guaranteed by the FHA, FHA lenders cannot seek a deficiency judgment, such that FHA loans may be particularly poorly suited to studying the effect of recourse on default behavior.

Other related papers include Crawford and Rosenblatt (1995), Ambrose, Buttimer, and Capone (1997), and Corbae and Quintin (2010). Crawford and Rosenblatt (1995) find that, conditional upon default occurring, loss severity is greater in non-recourse states. Our empirical results corroborate Crawford and Rosenblatt (1995) since we find that borrowers in recourse states are more likely to default through a lender-friendly method. Ambrose, Buttimer, and Capone (1997) and Corbae and Quintin (2010) study theoretically the effect of deficiency judgments on default and find that recourse deters default. Our empirical results support these theoretical predictions.

The remainder of the paper proceeds as follows: The next section describes how lender recourse varies across the U.S. states. Section 3 describes our data and variables. Section 4

[1] Pence (2006) examines differences in average loan size in census tracts that span two states and finds that the average loan size is smaller in states with more defaulter-friendly foreclosure laws.

shows how recourse affects whether default occurs. Section 5 explores how recourse changes the way default occurs. In Section 6, we look at whether recourse is priced. Section 7 concludes.

2 Foreclosure Law and Default

2.1 Foreclosure Law Across the U.S. States

States vary in the statutes governing how much recourse the lender has in the event the lender forecloses on the property and the proceeds from the foreclosure sale are not sufficient to cover the borrower's debt. States also differ in how long it takes the lender to foreclose.

In most states, the lender may obtain a deficiency judgment to cover the difference between the balance owed and the value of the home in the event the lender must foreclose in a negative equity situation. In states that permit deficiency judgments, various restrictions often apply. Usually, the lender must credit the borrower's account for the fair market value of the property rather than the foreclosure sale price. The fair market value restriction is likely present because the lender is often the only bidder at the foreclosure sale (see, for example, Brueggeman and Fisher [2011]). In the absence of such a restriction, the lender could profit from a foreclosure by bidding an artificially low price. In addition to lowering the likely recovery from a deficiency judgment, such restrictions sometimes mean that the lender must incur substantially higher legal costs and spend more time pursuing a deficiency. The increase in costs and time depends on state statutes governing the determination of fair market value. In some states, a single appraiser determines fair market value. In other states, such as Minnesota, fair market value must be determined by a jury. Finally, states differ in how easy it is for the borrower to contest the fair market value of the property.

Lenders have less recourse in practice in states that require lenders to go through a lengthy judicial foreclosure process, rather than a quicker non-judicial foreclosure process, to obtain a deficiency judgment. In other states, such as Idaho and Nebraska, there is a relatively short period in which the lender can file. In some states, substantial personal property or wages are exempt from collection on the deficiency. Finally, in Ohio and Iowa, the lender

has a relatively short period in which to collect on the deficiency after the foreclosure sale.

In states that allow deficiency judgments, a borrower retains the option to declare bankruptcy and have some or all of the deficiency judgment discharged. As White (1998) reports, prior to the 2005 bankruptcy reform act, most unsecured debts were discharged in bankruptcy regardless of whether the borrower filed under Chapter 7 or under Chapter 13. Furthermore, filing for bankruptcy had a low pecuniary cost before the 2005 act, such that the major cost of filing for bankruptcy was reduced availability of credit. In Chapter 7 filings, it continues to be the case that deficiency judgments are completely discharged and, if the Chapter 7 filing is concurrent with a foreclosure, the lender loses the right to a deficiency judgment. In Chapter 13 filings, the lender may pursue a deficiency judgment. Following the 2005 bankruptcy reform, however, borrowers with incomes above the state median income usually must file under Chapter 13, rather than Chapter 7, which might make it more difficult to discharge a deficiency judgment for high income borrowers.

A few states explicitly forbid deficiency judgments on most homes (e.g., Arizona and Oregon) or on purchase mortgages. In other states, the restrictions on deficiency judgments are so onerous that it is highly impractical for the lender to pursue a judgment in the vast majority of cases, which makes the state effectively non-recourse. Table 1 summarizes the extent of recourse the lender has in each state and the time it takes the lender to complete the foreclosure process if the borrower does not contest the foreclosure. We classify Alaska, Arizona, California, Iowa, Minnesota, Montana, North Carolina (purchase mortgages), North Dakota, Oregon, Washington, and Wisconsin as non-recourse states.[2]

Our classification of states is similar to that of the USFN (America's Mortgage Banking Attorneys). The states we classify as non-recourse are the same as those for which the USFN (2004, pp. 5-5 - 5-7) indicates that a deficiency judgment is either not available or highly impractical. However, we classify purchase mortgages in North Carolina as non-recourse since state law prohibits deficiency judgments on purchase mortgages. We treat South Dakota as a recourse state. To help us determine the recourse classification, we usually were able to speak with at least one foreclosure attorney in each state where the amount of recourse in

[2] Appendix A describes the foreclosure and deficiency judgment procedures in the U.S. states. We use the foreclosure timelines from the National Mortgage Servicer's Reference Directory (2004) published by the USFN (America's Mortgage Banking Attorneys).

practice was unclear, or the statutes were difficult to understand.

2.2 Types of Default

In this paper, we use the term default to refer to a default that ends with the borrower vacating the home. In practice, lenders usually view litigious foreclosure as a last resort when the borrower defaults and will often try to recover a portion of principal through other means before resorting to foreclosure.[3] When the lender does choose to exercise the option to foreclose, lenders have a strong interest in foreclosing quickly on the property.[4]

Lenders prefer to avoid foreclosures, especially contested foreclosures, for several reasons. First, properties depreciate substantially when the borrower is in default. Second, the property usually sells at a distressed value in a foreclosure sale. Third, lenders may incur negative publicity and reputation costs among other prospective borrowers by forcibly removing a borrower from his or her home. For instance, Campbell, Giglio, and Pathak (2010) find that a foreclosure reduces the value of the home by approximately 27%. The depreciation rate is faster when a property is in default because the borrower has no incentive to adequately maintain the property and thus may deliberately accelerate the property's depreciation.

There are at least three lender-friendly ways for a borrower to default: a short sale, a voluntary conveyance, or simply agreeing not to contest the foreclosure. In a short sale, the borrower finds a buyer for the property who pays a purchase price that is less than the full balance of the debt owed. The lender agrees to waive his right to a deficiency in exchange for the borrower selling the property and remitting the proceeds to the lender. Occasionally, the lender may only agree to waive his right to a deficiency if the borrower agrees to give the lender a lump sum payment in addition to the sale proceedings.

In a voluntary conveyance, the borrower hands over the deed to the property to the lender. In the most common voluntary conveyance, a deed in lieu, the lender forgives the debt owed in exchange for the deed. In addition to eliminating the risk of the lender pursuing a deficiency judgment, a deed in lieu may affect a borrower's future access to credit less severely than

[3] See, for example, Larsen, Carey, and Carey (2007), Brueggeman and Fisher (2008), and Ling and Archer (2008).

[4] This view was also prevalent among the foreclosure attorneys to whom we spoke.

a forcible eviction (Larsen, Carey, and Carey [2007]). The benefit to the lender is that, in addition to getting the property back more quickly, the lender's legal costs are lower and the deed in lieu of foreclosure "can be beneficial to the lender's public image and to the public perception of the property" (Ling and Archer [2008]).

However, a voluntary conveyance carries some risks to the lender. First, if the borrower declares bankruptcy within one year of a deed in lieu, the court may declare the conveyance improper. In such a case, the lender's claim becomes an unsecured claim on the borrower's assets and, in the case of a Chapter 13 filing, on the borrower's future income, which will generally give the lender a worse payoff. Second, a voluntary conveyance does not cut off any subordinate liens on the property the way a foreclosure does.

Finally, a borrower may simply agree to what is known as a "friendly foreclosure." In a friendly foreclosure, the borrower agrees to not contest the foreclosure and to submit to the jurisdiction of the court regarding leaving the property and cooperating with the lender. The main benefit of this option is that the lender gets the property back more quickly than in a contested foreclosure. This takes more time than a voluntary conveyance but is less time-consuming than a standard foreclosure (Brueggeman and Fisher [2011]). A friendly foreclosure may be preferable to the lender because it cuts off any subordinate interests that may exist on the property and protects the lender if the borrower subsequently declares bankruptcy (Ling and Archer [2008]). The benefits to the borrower from a friendly foreclosure relative to a more standard foreclosure are similar to those from a short sale and a deed in lieu: the lender usually agrees to waive his or her right to a deficiency judgment.

Subsequent to a voluntary conveyance, the property becomes real estate owned (REO), i.e., the lender owns the property. A property can also become REO subsequent to a foreclosure sale if the lender acquires the property by virtue of being the only bidder.

3 Data

The data used in the study are loan-level data from LPS Applied Analytics, Inc. The data contain information on prime and non-prime private securitized loans, portfolio loans, and GSE loans on a monthly basis. Appendix B provides details about the variables by LPS

codes.

3.1 Variable Definitions

3.1.1 Definition of Default

We define the loan as defaulted if it is terminated in one of the following ways: by REO sale, by short sale, by payoff out of foreclosure, by payoff out of bankruptcy and serious delinquency, or by liquidation to termination. In the analysis of the probability of default, the dependent variable takes a value of 1 in the month the loan defaults. We drop all observations on defaulted loans subsequent to the default month. Consequently, the dependent variable takes a value of 0 for observations in months prior to default for defaulted loans and for all observations on loans that do not default.

3.1.2 Default Type

In the analysis of whether recourse changes how default happens, we consider only defaulted loans. We divide defaults into default by foreclosure and default by a lender-friendly method, i.e., a short sale or a deed in lieu. We define a default as lender-friendly if the loan passes directly to an REO loan or a short sale. We define a default as a foreclosure if the lender receives a payoff out of bankruptcy or serious delinquency. Such a default is akin to a contested foreclosure process since the borrower likely declares bankruptcy to halt foreclosure proceedings. The default type variable takes a value of 1 if the loan defaulted via a foreclosure and 0 otherwise.

3.1.3 Default Option Variables

We define the value of the default option as the probability that the borrower has negative equity in the house as in Deng, Quigley, and Van Order (2000) and Ambrose, Capone, and Deng (2001). Since we know the balance owed on the loan, we need only to infer the distribution of individual house prices. The value of equity to market value k_i months after loan i's origination is

$$E_{i,t,k_i} = \frac{M_{i,t,k_i} - L_{i,t,k_i}}{M_{i,t,k_i}},$$

where M_{i,t,k_i} is the market value of the property purchased at time $t - k_i$, and L_{i,t,k_i} is the present value of the remaining loan balance. The market value of the property is

$$M_{i,t,k_i} = C_i \frac{HPI_{i,t}}{HPI_{i,t-k_i}},$$

where $C_{i,t-k_i}$ is the cost of the property at the time of a purchase, $HPI_{i,t}$ is house price index in the state where the property associated with mortgage i is located, and $\frac{HPI_{i,t}}{HPI_{i,t-k_i}}$ follows a lognormal distribution (see Case and Shiller [1987] and Deng, Quigley, and Van Order [2000] for details). The mean and variance of $\frac{HPI_{i,t}}{HPI_{i,t-k_i}}$ is obtained using the data available from the Office of Federal Housing Enterprise Oversight (OFHEO).[5]

The value of the default option for mortgage i k_i months after origination is the probability that equity is negative:

$$Default\_Option_{i,k_i} = \Pr(E_{i,t,k_i} < 0) = \Phi\left(\frac{\ln L_{i,k_i} - \ln M_{i,k_i}}{\sqrt{\sigma^2_{HPI_{i,k_i}}}}\right),$$

where $\Phi(\cdot)$ is the cumulative standard normal distribution and $\sigma^2_{HPI_{i,k_i}}$ is the variance of individual house prices in the state in which the property associated with mortgage i is located. As in Deng, Quigley, and Van Order (2000), we include the default option linearly and squared.

3.1.4 Prepay Option Variables

As a proxy for the prepayment option, we use a spread between the current market mortgage rate, r_t, and the mortgage rate on the contract, r_0. We use indicator variables, rather than a continuous variable, based on the results of Kau, Keenan, and Kim (1994) showing that the spread affects default rates in a nonlinear fashion. Following Ambrose, Capone, and Deng (2001), we define the following dummy variables: Rate1 = 1 if r_0+2% $\leq r_t$, and 0 otherwise; Rate2 = 1 if $r_0 + 1\% \leq r_t < r_0 + 2\%$, and 0 otherwise; Rate3 = 1 if

[5] To calculate the standard deviation of $\frac{HPI_{i,t}}{HPI_{i,t-k_i}}$, $\sigma_{HPI_{i,k_i}}$, we use the volatility parameters A and B provided by OFHEO as follows:

$$\sigma_{HPI_{i,k_i}} = \sqrt{Ak_i + Bk_i{}^2}.$$

See Calhoun (1996) for the technical description of OFHEO index.

$r_0 - 1\% \leq r_t < r_0 + 1\%$, and 0 otherwise; Rate4 = 1 if $r_0 - 2\% \leq r_t < r_0 - 1\%$, and 0 otherwise; and Rate5 = 1 if $r_t < r_0 - 2\%$, and 0 otherwise, where r_t and r_0 are in percentages.

3.1.5 Foreclosure Timing and Recourse Variables

We include the time it takes to complete an uncontested foreclosure in the state in which the property is located. Table 1 contains our benchmark recourse classification of states and the foreclosure timelines. We classify North Carolina purchase mortgages as non-recourse and other mortgages on property located in North Carolina as recourse.

3.1.6 Trigger Events

We control for trigger events by including the contemporaneous state divorce rate and the state unemployment rate. We use lagged monthly seasonally unadjusted unemployment rates from the BLS.[6]

3.1.7 Loan Level Variables and Borrower Characteristics

Additional variables that we use in the empirical analysis are the age of the loan (in months), the LTV at origination, an indicator variable that takes a value of 1 if the loan is interest only at origination, an indicator variable that takes a value of 1 if the loan is an adjustable rate mortgage (ARM), an indicator variable that takes a value of 1 if the loan is a jumbo, an indicator variable that takes a value of 1 if the loan is not a purchase mortgage, and the borrower's FICO score at origination. We convert nominal appraisal amounts at origination into real 2005 dollars by deflating using the CPI excluding shelter.

Since a mortgage with an 80% LTV at origination may indicate a higher likelihood of a second mortgage being present, we include a dummy variable that takes on a value of 1 if the LTV is exactly equal to 80%. We also include interactions of this variable with the default option value and its square since, if an LTV of 80% makes it more likely that the property has a second mortgage, the default option value is in fact higher for these mortgages such that it may have a stronger effect on the probability of default. See Foote, Gerardi, Goette,

[6] We do not use seasonally adjusted unemployment rates as there may be a seasonal pattern to defaults due to seasonal economic conditions.

and Willen (2009) for empirical evidence that an LTV of exactly 80% increases the risk of default.

3.2 Sample Description

We use information on loans originated between August 1997 and December 2008. August 1997 is the first month that the FICO score variable is available in the data. We restrict our analysis to first mortgages with constant principal and interest, ARMs, or graduated payment mortgages on single-family residences, townhouses, or condos. We drop all FHA and VA loans because deficiency judgments are prohibited on FHA loans and strongly discouraged on VA loans (Larsen, Carey, and Carey [2007]). We also drop loans with private mortgage insurance.

We then draw a 10% random sample from the LPS database. Our restrictions imply that we have 85,888,286 loan-month observations. In total, our sample includes 2,922,196 loans and 43,353 defaults.

Table 2 provides a summary of the sample: 67% of our observations are on recourse mortgages; on average there is a 1% probability that a home owner in our sample has negative equity; 7% of our observations are interest only at origination; and 20% of our observations are adjustable rate mortgages. The unconditional default rates are similar in recourse and non-recourse states: in both recourse and non-recourse states, about 1.5% of loans in our sample terminate through a foreclosure, a deed-in-lieu, or a short sale. Borrowers in recourse states have slightly lower average FICO scores, slightly higher LTVs at origination, somewhat lower appraisal amounts, and face lower risks of divorce or unemployment. Borrowers in non-recourse states are more likely to have an interest-only mortgage, an adjustable rate mortgage, and higher default option values. The fraction of mortgages with an LTV of exactly 80% is the same across recourse and non-recourse states.

4 The Impact of Recourse on Default

We use a probit as our benchmark model to study the effect of recourse on whether a borrower defaults. We assume that the borrower defaults if an unobserved variable x,

$x = X\beta + \varepsilon$, falls below 0 where $\varepsilon \sim N(0,1)$. X is a vector of variables that controls for the borrower's prepay and default options, other loan-level characteristics, and trigger event variables.

The first column of Table 3 contains the results without recourse variables. The results in the column illustrate the effect of the prepay and default options, trigger events, and loan-level characteristics on default when we do not control for recourse. All of the coefficients have the expected sign. Having an interest-only loan, an ARM, or a purchase mortgage raises the probability of default. Borrowers with higher FICO scores at origination are less likely to default while loans with a high LTV at origination are more likely to default. Finally, younger loans are much more likely to default than older loans. The divorce rate has the expected sign but is significant only at the 10% level when we cluster the standard errors, likely because there is relatively little variation across time in the divorce rate within a state. The unemployment rate has the expected sign but becomes insignificant when the standard errors are clustered.

Unconditionally, we found no difference in the default rate between recourse and non-recourse states (see Table 2). In column 2 of Table 3, we examine whether the lack of a difference in default rates across recourse regimes is due to differences in loan characteristics, default option values, or prepay option values. The recourse dummy variable takes a value of 1 if the mortgaged property is located in a state with a provision for recourse and 0 otherwise. The coefficient on recourse is statistically insignificant at the 10% level. The results thus suggest that states that allow the lender recourse do not in fact have fewer defaults contrary to Feldstein's hypothesis. However, the lack of significance of recourse in levels may be due to other differences across states in either the legal or economic environment.

Recourse directly affects the borrower's payoff from defaulting. Different payoffs from the default decision in recourse and non-recourse states may lead to different threshold values of the default option at which the borrower defaults in recourse and non-recourse states. Thus, the appropriate specification with which to estimate the impact of recourse on the probability of default models recourse as an interaction term between the value of the default option and the recourse indicator variable.

Column 3 of Table 3 contains the main result of the paper. The coefficient on the

interaction term between recourse and negative equity is negative and statistically significant. The coefficient on the interaction between recourse and the square of the probability of negative equity is positive and statistically significant. The negative coefficient on the default option value indicates that recourse decreases the impact of the negative equity on the probability of default. The positive coefficient on the squared term indicates that the effect decreases as the default option value increases. Because of this nonlinear effect of default option value on the probability of default, the effect of recourse depends on a particular value of the default option.

The coefficient on the interaction between the default option value and the dummy for an LTV of exactly 80% is significant and positive, suggesting that properties with mortgages that have an LTV of exactly 80% are more likely to have second mortgages attached to them (see Foote, Gerardi, Goette, and Willen [2009]), and that first mortgages are thus more sensitive to negative equity. It is important that we include this term to ensure that our results are not driven by the fact that there may be more second mortgages in non-recourse states than in recourse states.[7]

In column 4 of Table 3, we include recourse in levels as well as in interactions with the default option value. The coefficient on the interaction between the default option value and recourse is again negative and highly significant. It is only slightly smaller in magnitude than in the specification in column 3 where we include recourse only in interactions. In contrast, the coefficient on recourse in levels falls substantially and is far from statistically significant. The results corroborate the hypothesis that recourse affects the payoff from defaulting; recourse only affects a state's default rate through decreasing the borrower's sensitivity to the put option.

In column 5 of Table 3, we explicitly incorporate the sorts of state-specific factors that recourse in levels likely captures by including state dummy variables.[8] This enables us to ensure that our results regarding the effect of recourse on the borrower's sensitivity to the default option are not due to state-specific factors. When we control for the state-

[7] All our results are similar when we do not include the LTV80 variable and its interactions.

[8] We drop the divorce rate in this specification as our divorce rate data are only available at the annual frequency. Also, for some states, we only have a few divorce rate observations over the entire sample such that there is little variation remaining in the divorce rate after we control for state-specific effects.

specific fixed effects, the results on the effect of recourse carry through: the coefficient on the interaction between recourse and the default option value is statistically significant, negative, and slightly larger in magnitude than in the benchmark specification. Thus, our results regarding the deterrent effect of recourse are not driven by unobserved differences between recourse and non-recourse states.

To gauge the magnitude of the deterrent effect of recourse, we evaluate the probability of default in recourse and non-recourse states at different values of the default option. Table 4 contains the estimates of the probabilities. Columns 1 through 4 show the probabilities at the means of the continuous variables and the modes of the dummy variables. At the mean of the default option for all observations, the probability of default is 6% higher in non-recourse states than in recourse states. At the 90th percentile of the value of the default option for all observations, the probability of default in non-recourse states is 2% higher. This difference increases to 13% at the 95th percentile.

The results in Table 4 indicate that recourse has a deterrent effect on default at high values of the default option value, which are precisely the values associated with default. At the mean of the default option at the time of default, borrowers in non-recourse states are 32% more likely to default than borrowers in recourse states. Thus, the data allow us to reject the hypothesis that recourse has no effect on default.

4.1 Alternative Specifications

In columns 2 through 4 of Table 5, we present the results for two alternative specifications. In column 2, we include the prepay option - the difference between the contract rate and current mortgage rates - in interactions with the probability of negative equity as in Ambrose, Capone, and Deng (2001). The results are similar to our benchmark specification, although the log-likelihood is somewhat higher when rates are included in interactions, suggesting that including rates in levels fits the data better.

4.1.1 Foreclosure Timing

In column 3 of Table 5, we show the effect of the lengthiness of the uncontested foreclosure process, as stated in USFN (2004), on the probability of default. In column 3 we include the length (in months) of the uncontested foreclosure process for the state in which the property is located. When we do not cluster the standard errors, states with lengthier foreclosure processes appear to experience more defaults. However, the effect becomes insignificant when we cluster the standard errors by state. We also do not find that the lengthiness of the foreclosure process significantly affects default in other specifications in which we include the interaction of the foreclosure timeframe with recourse. We obtain similar results with a specification in which we include foreclosure timing by using a dummy variable that takes on a value of 1 if the state's uncontested foreclosure process takes more than 6 months and 0 otherwise.

4.1.2 A Finer Recourse Classification

In our benchmark specification, we define mortgages as being either recourse or non-recourse. Our benchmark classification (see Table 1) defines a mortgage as non-recourse if deficiency judgments are either explicitly prohibited or impractical in the vast majority of cases. We also consider a finer classification of non-recourse. In this specification, we categorize a mortgage as being non-recourse if it is *de jure* (i.e., explicitly) non-recourse and a mortgage as being subject to limited recourse if the mortgage is *de facto* non-recourse. We define mortgages on property in Arizona, North Dakota, and Oregon, as well as purchase mortgages in California, Montana, and North Carolina, as *de jure* non-recourse. We define California and Montana non-purchase mortgages as well as mortgages on property in Alaska, Iowa, Minnesota, Washington state, and Wisconsin as *de facto* non-recourse.

In column 4 of Table 5, we present the results from the specification in which we use the finer recourse classification: recourse (same mortgages as in the benchmark specification), *de facto* non-recourse, and *de jure* non-recourse. The omitted category is *de jure* non-recourse; limited recourse is a dummy variable that takes a value of 1 if the mortgage is *de facto* non-recourse and 0 otherwise. The coefficient on recourse remains significantly negative and is

slightly larger in magnitude than in our benchmark specification. The coefficient on limited recourse is significantly negative but much smaller in magnitude than the coefficient on recourse. Thus, default is more likely if the mortgage is *de jure* non-recourse than if it is *de facto* non-recourse. However, default is more likely if the mortgage is *de facto* non-recourse than if it is recourse.

4.2 Robustness

We conduct several additional robustness exercises. First, we repeat our analysis using only data on mortgages originated from 2005 onwards. There is some concern that the data is of higher quality from 2005 onwards. Additionally, a very large mortgage servicer enters the database in 2005. Column 1 of Table 6 presents the results from our benchmark specification but using only data on originations from 2005 to the end of our sample. Column 2 presents the results using our specification that includes state fixed effects using only data on originations from 2005 to the end of our sample. The results are consistent with those we obtain using our benchmark specification. The full set of results using only data from 2005 onwards is an appendix available from the authors.

Columns 3 through 5 of Table 6 contain the additional results from the full sample. Column 3 contains the results from a specification in which we include dummies for the year of origination. The coefficient on the interaction between the default option value and recourse is similar to that of our benchmark specification in column 3 of Table 3. With 2003 as the omitted category, the coefficients on origination years from 1998 to 2001 are negative and statistically significant while the coefficients on 2004, 2005, and 2006 are positive and statistically significant. These results provide some evidence that, controlling for a set of variables used in our benchmark specification, the mortgages originated in the later years of the sample, particularly from 2004 to 2006, have a higher probability of default than the mortgages originated earlier.

In columns 4 and 5 of Table 6, we present proportional competing hazard models (see, for example, Deng, Quigley, and Van Order [2000]). In our benchmark specification, we use a probit model and control for time-dependence with the time elapsed from loan origination. Thus, our benchmark specification provides an estimate of the probability of the loan

defaulting in any particular month. Alternatively, we can estimate the hazard model of the risk of default.

Generally, a mortgage can be terminated by default or prepayment such that a mortgage is subject to two competing hazards. Column 4 of Table 6 contains the results (for default) from fitting models for each termination type separately and treating failures due to a competing type of termination as censored data. The hazard ratio on the interaction between recourse and the default option is below 1 and highly significant, indicating that recourse reduces the sensitivity of default to negative equity as we found using our benchmark specification.

We also estimate the two hazard functions jointly. To do so, we assume that the two competing hazard functions are additive. Consequently, the hazard of failure by any termination type is a sum of the two competing processes. The observed time of failure is the minimum time of failure of the two competing processes. Thus, at the time of failure, two survival times are observed: one for a process that corresponds to the failure type and another one, censored, for the competing process.

We use a proportional hazard model with grouped duration data. To estimate the competing hazards of default and prepayment, we duplicate the data using the method in Lunn and McNeil (1995). The duplicated data set contains twice as many observations as the original one, with each new observation showing a censored observation for a competing termination type. The censored observations are also duplicated, creating two censored observations – one for each failure type. We then define a variable that identifies two strata: one for prepayment and one for default. The failure indicator then reflects failures from a type of termination corresponding to the respective stratum. We estimate the semi-parametric Cox model including, in addition to our benchmark covariates, a strata indicator as a covariate, as well as interactions of the strata indicator with all covariates. Inclusion of the strata indicator as a covariate assumes proportional baseline hazards for the two competing types of termination while allowing the effect of covariates on the hazard to differ.

Column 5 of Table 6 presents the results for default from the joint estimation of the competing hazards model. The results from estimating competing hazards jointly are similar to those obtained from estimating the hazards separately. The hazard ratio on the interaction between recourse and the default option is below 1 and highly statistically significant.

We also estimate a version of our model where the default option enters non-parameterically. The results are very similar to those in our benchmark specification and are in an appendix available from the authors.

4.3 Results by Appraisal Amount

The deterrent effect of recourse on default depends on the lender's recovery rate, i.e., the fraction of the deficiency judgment that a lender can actually recover. We proxy for the lender's recovery rate with the appraised value of the mortgaged property. A higher appraised value likely indicates that the borrower has more assets that the lender can use to recover on the deficiency judgment. Additionally, a higher appraisal amount is more likely to be associated with higher income since the ratio of debt to income is a key ratio in the underwriting process. Higher-income borrowers who declare bankruptcy also may have less chance to have their debt discharged during bankruptcy proceedings. This is particularly true for borrowers considering default after the 2005 bankruptcy reform, which usually requires borrowers above the state median income to file under Chapter 13 rather than under Chapter 7. This implies that, unlike with poorer borrowers, lenders have better recovery rates with richer borrowers. In fact, our examination of the data from the Survey of Consumer Finance indicates that there is a positive relationship between the median value of the primary residence and financial (non-housing) wealth. In 2007, households in the lowest quintile of financial (non-housing) wealth held homes worth $81,946 on average, while households in the second, third, fourth, and fifth quintiles of non-housing wealth held homes worth on average $118,367, $154,788, $191,208, and $318,681, respectively (in real 2004 dollars).

Table 7 contains the results of estimating our benchmark specification separately for different values of the appraised value (real 2005 dollars) of the mortgaged property at origination. As the results in Table 6 show, recourse does not deter default for all households in the same way. Recourse is a deterrent for default when the appraisal amount exceeds $200,000: the coefficient on the recourse interaction with the default option value and its square are statistically insignificant when the appraisal amount is $200,000 or less. The coefficient on the interaction of the recourse with a linear default option term is particularly

large in the samples with appraisal amounts from $300,000 to $500,000 and from $500,000 to $750,000. For the sample with appraisal amounts of $1,000,000 or higher, the coefficient changes sign and is not statistically significant.

The results of the estimation of the probability of default in the samples by appraisal amount indicate that the effect of recourse on the probability of default is mainly driven by borrowers with mortgages on properties appraised at $200,000 and higher. To the extent that the appraisal amount at origination proxies for the recovery rate on a deficiency judgment, these results indicate that recourse has a substantial deterrent effect on default in cases with higher recovery rates**.** Recourse does not have a statistically significant effect when the recovery on a deficiency judgment is likely to be low.

To gauge the magnitude of the deterrent effect of recourse on the default probabilities, we present estimates of the probabilities of default in recourse and non-recourse states in Table 4. At the mean value of the default option at the time of default and for homes appraised at $300,000 to $500,000, borrowers in non-recourse states are 81% more likely to default than borrowers in recourse states. For homes appraised at $500,000 to $750,000, borrowers in non-recourse states are more than twice as likely to default as borrowers in recourse states. For homes appraised at $750,000 to $1 million, borrowers in non-recourse states are 60% more likely to default than borrowers in recourse states.

Importantly, the size of the deficiency judgment relative to the lender's fixed cost of filing for a deficiency is likely to be lower for low-value properties than for high-value properties. This lowers the incentive for a lender to file for a deficiency judgment for low-value properties. If the recovery rate is 100%, costs do not matter because they are recoverable. However, if the recovery rate is less than 100%, the effect of allowing the lender recourse depends on the cost of pursuing the deficiency judgment as well as the recovery rate; the effect of costs decreases as the recovery rate increases. As a result, the finding that recourse does not have a deterrent effect on default for low-value properties is consistent with costs being an important determinant of the effect of allowing lenders recourse.

4.4 Recourse and Lender Types

Table 8 presents the results from the probit regression estimated separately for loans held by Fannie Mae (FNMA), loans held by Freddie Mac (FHMLC), loans that are privately held and securitized, and loans held in a bank's portfolio. As seen in Table 8, the coefficient on the interaction of the recourse dummy with the default option value is negative, sizeable, and statistically significant for privately securitized and private portfolio loans. Table 4 presents estimates of the probabilities for recourse and non-recourse states. At the mean value of the default option at the time of default and for securitized privately held loans, borrowers in non-recourse states are 45% more likely to default than borrowers in recourse states. For privately held portfolio loans, borrowers in non-recourse states are 44% more likely to default.[9]

The estimation results in Table 8 indicate that recourse does not have a significant deterrent effect on default for loans held by FNMA or FHMLC. The coefficients on the interaction between the default option value and recourse for the FNMA and FHMLC samples are much smaller in magnitude than the ones for privately securitized loans and are statistically insignificant. This is true even when we consider only FNMA and FHMLC loans on properties appraised at $200,000 or more (in real 2005 dollars), the threshold above which we find that recourse matters. We conclude that recourse has a statistically significant deterrent effect on default only for privately held loans.

4.5 Recourse and Expected LTVs

Table 9 presents the results from the probit regression when we use the current expected LTV as a proxy for the default option rather than the probability of negative equity as in our benchmark specification. The expected LTVs are computed using average home prices. The results are similar to the results we obtain from our benchmark specification. In the full sample, the coefficient on the interaction between recourse and the expected LTV is statistically significant at the 10% level; the effect is highly significant for higher appraisal

[9] We also estimate our benchmark specification on FHA and VA loans. Since these loans are explicitly non-recourse in all states, we should not find a significant negative coefficient on the interaction between recourse and the default option value. We find that the coefficient on the interaction between recourse and the default option value is positive, albeit small, for FHA and VA loans.

values.

In Table 10, we use the results in Table 9 to compute the increase in the expected LTV in a recourse state relative to the expected LTV in a non-recourse state such that the default probability in both states is the same. In the full sample, the effect of recourse is to increase the expected LTV at which a borrower defaults by 8.6%. The equivalent expected LTV in a recourse state rises to 22% for mortgages on properties appraised at $\$300,000$ to $\$500,000$ and to 24% for mortgages on properties appraised at $\$500,000$ to $\$750,000$.

5 The Impact of Recourse on the Default Method

We next turn to the question of how lender recourse affects the way in which default occurs. First, we examine whether recourse makes it more likely that a borrower defaults through a deed in lieu or a short sale. To the extent that deeds in lieu and short sales represent more lender-friendly defaults than foreclosures, we expect defaults to occur more frequently by these methods in recourse states because the lender can use the threat of a deficiency judgment as a negotiating tool. We have in mind a bilateral bargaining model in which recourse affects the borrower and lender's payoffs from defaulting.[10] The results corroborate our hypothesis. We then look at whether recourse makes it more likely that borrowers cure their defaults. We find that the cure rate is higher in recourse states. Finally, we find that borrowers that default in recourse states are more likely to attempt to resume payments during the delinquency that precedes the foreclosure.

5.1 Recourse, Deeds in Lieu, and Short Sales

We estimate a probit model to determine which factors influence whether borrowers are more likely to default by foreclosure rather than by a deed in lieu or a short sale. The sample is restricted to the observations for which the default variable takes a value of 1. The dependent variable takes a value of 1 if the default is by a foreclosure and 0 otherwise.

Borrowers may be less likely to default by foreclosure in states with recourse. They may also be more likely to default by friendly foreclosure than by contested foreclosure in recourse

[10] The full model and its solution are in an appendix available from the authors.

states. However, we are unable to empirically distinguish between friendly foreclosures and contested foreclosures. To test the hypothesis that recourse influences how the borrower defaults, we include a recourse variable dummy as an explanatory variable for the probability of default by foreclosure. As controls, we include the borrower's FICO score at origination and the LTV at origination to control for unobserved heterogeneity in the borrower's costs of decreased access to credit or search costs. Column 1 of Table 11 contains the results of the estimation. As the results indicate, recourse lowers the probability of default by foreclosure. The estimated coefficient is negative and statistically significant. In particular, the probability of default by foreclosure in recourse states is 10% lower than the probability in non-recourse states.[11]

The effect recourse has on the way a borrower defaults depends on how much recourse the lender has, as well as the LTV at the time of default. However, the relationships are nonlinear. For high LTVs and high recovery rates, the deterrent effect of a deficiency judgment is strong enough to deter default altogether. For high LTVs and more moderate recovery rates, it is sometimes worthwhile for the lender to pursue a deficiency judgment and for the borrower to default. For moderate LTVs and low-to-moderate recovery rates, recourse changes how the borrower defaults rather than if the borrower defaults.

To test whether recourse has a stronger effect for higher values of the default option value, we add the default option value and the default option value interacted with the recourse dummy, in addition to the recourse variable, as the explanatory variables for the probability of default by foreclosure. If recourse has a stronger negative effect at higher values of the default option, we expect a negative coefficient on the interaction term between recourse and the default option value. As can be seen from the results in column 2 of Table 11, the negative effect of recourse on the probability of default by foreclosure is stronger for higher values of the default option. However, the effect is not statistically significant.

Theory does not provide a clear prediction regarding the effect of the time it takes to foreclose on the share of lender-friendly defaults. On the one hand, a longer foreclosure process makes it more likely that the lender will prefer a lender-friendly default to a foreclosure and will forgo a deficiency judgment in favor of a deed in lieu or a short sale. On

[11] We calculate the partial effects at the mean of continuous variables and at the modes of dummy variables.

the other hand, the borrower prefers foreclosure when he can delay the search and credit costs and receive a longer period of free rent as a result of a lengthier foreclosure process. A priori, it is unclear what effect foreclosure timing will have on the process. To examine the effect empirically, we include a dummy variable that takes a value of 1 if the uncontested foreclosure time is less than six months, and zero otherwise. As the results in column 3 of Table 11 indicate, the foreclosure timing does not have a significant effect on the probability of default by foreclosure: the partial effect evaluated at the means implies an increase in probability of 2% and is far from statistically significant. The results were very similar when we included foreclosure timing as a continuous variable rather than as a dummy variable.

Finally, we examine whether lender type and the appraisal amount affect the probability to default by litigious foreclosure. To examine the effect of lender type, we include a dummy variable that takes a value of 1 if the lender is a GSE and 0 otherwise, i.e., when the loan is privately securitized or held in a private lender's portfolio. As can be seen from the results in column 4 of Table 11, mortgages held by a GSE are no more likely to default by foreclosure than mortgages held by private lenders.

To examine the effect of the appraisal amount of the property on the probability of default by foreclosure, we include the appraisal amount and the appraisal amount interacted with the recourse dummy as explanatory variables. We present the estimation results in column 5 of Table 11. The coefficient on the appraisal amount is positive and marginally significant. The coefficient on the interaction term with recourse is negative but statistically insignificant.

5.2 Cure Rates

We examine whether borrowers in recourse states are more likely to remedy their delinquencies using the methodology developed by Adelino, Gerardi, and Willen (2009). A cured loan is one that is prepaid, current, or 30 days delinquent 12 months after the initial 60-day delinquency. As in Adelino, Gerardi, and Willen (2009), we restrict our analysis to the first 60-day delinquency; we do not look at cures on any subsequent 60-day delinquency.

In the full sample, 42% of loans in non-recourse states cure while 57% of loans in recourse states cure. We also examine cure rates in different product categories. For interest-only

loans, the cure rates in non-recourse and recourse states are 25% and 35%, respectively. For adjustable rate mortgages, the cure rates in non-recourse and recourse states are 36% and 49%, respectively. The cure rates for fixed rate mortgages are 50% in non-recourse states and 62% in recourse states. We also look at whether other loan and borrower characteristics explain the difference in cure rates between non-recourse and recourse states. The difference between cure rates remains after we control for such characteristics, although the effect is not always statistically significant.

The fact that borrowers are more likely to cure their delinquencies in recourse states may indicate that borrowers are not always aware that the mortgage is recourse until after they become delinquent. They may learn that their loan is recourse after the initial delinquency from the servicer of the loan, after consulting a foreclosure attorney, or perhaps both. Indeed, in delinquency notifications, servicers generally inform the borrower that a mortgage is recourse if this is the case. After learning that the cost of default is higher than first anticipated, the borrower may then make greater efforts to stay current or decide against a strategic default. However, it is also possible that the higher cure rate reflects the fact that a greater share of defaults in recourse states are driven by liquidity constraints; if the borrower's liquidity constraints are relaxed after the initial delinquency, the cure rate will be higher in recourse states. We cannot disentangle these two possibilities; both channels are likely important in explaining the higher cure rate in recourse states.

5.3 Recourse and Direct Default

We now look at whether borrowers that default in non-recourse states are more likely to default directly, in the sense of abruptly stopping payments without any resumption of payments, than borrowers in recourse states. Foote, Gerardi, Goette, and Willen (2009) call such defaults "direct defaults" and suggest that these payment patterns are more prevalent among borrowers who default strategically. The intuition is that, in the absence of a sudden change in home price expectations, a borrower who decides to strategically default will simply cease making payments on the mortgage. If, instead, the borrower is defaulting because of a liquidity constraint, the borrower may resume payments if the constraint is relaxed in some month following the initial delinquency.

For example, a direct defaulter has a monthly payment pattern such as CCC3699999 where C denotes current in that month, 3 denotes 30 days delinquent in that month, 6 denotes 60 days delinquent in that month, and 9 denotes 90+ days delinquent in that month. Conversely, a defaulter who has a payment pattern such as CC333666999 or CC36369F is much less likely to be a strategic defaulter. In the first case, the non-strategic case, the fact that the borrower is three or six months delinquent in a row indicates that, despite having fallen behind on the mortgage, the borrower keeps sending monthly payments to the lender; he loses the home because he cannot keep up with payments. In the second case, the borrower gets two months behind on his mortgage and then makes two payments in one month, such that the lender codes him as 30-day delinquent once again.

To identify direct defaults, we focus on our sample of defaulted loans, where default is defined as a default that ends in the borrower losing the home. We first identify the month of a critical event. For loans that go into 90-day delinquent status prior to the borrower losing the home, the critical event is the first time at which the borrower goes 90-day delinquent with no subsequent resumption of payments prior to the borrower losing the home. Occasionally, we see a loan enter REO or F status without a prior 90-day delinquent status. Such cases of the borrower losing the home are likely due to either deeds-in-lieu or friendly foreclosures. For such loans, we define the critical event as the time the borrower loses the home.

We then define a direct default as a loan whose payment history satisfies the following two criteria: 1) In the six months prior to the critical event, the borrower records only one month of 30-day delinquency and only one month of 60-day delinquency, and 2) at no time in the loan's history prior to the six month stretch before the critical event was the borrower 60 or more days behind on his payments. Criterion 1 is identical to that of Foote, Gerardi, Goette, and Willen (2009). Criterion 2 is a somewhat more stringent criterion than that of these authors, since it excludes from direct defaults loans that were 60 days delinquent at some point in the past rather than only those loans that were "seriously delinquent" in the past.[12]

In our sample of defaulted loans, we find that 44% of defaults are direct defaults. In non-

[12] Foote, Gerardi, Goette, and Willen (2009) do not define exactly what they mean by seriously delinquent for this criterion but we assume they are excluding loans that were at least 90 days delinquent at some point in the past.

recourse states, 51% of defaults are direct defaults while only 39% of defaults in recourse states are direct defaults. Unconditionally, the share of defaults that are direct is 31% higher (12 percentage points) in non-recourse states than in recourse states.

In Table 12, we use a probit model to explore whether the higher share of direct defaults in non-recourse states is due to differences in loan characteristics, the default option value, the year in which default occurs, or differences in state foreclosure timelines. We include a dummy variable that takes a value of 1 if the critical event occurs in 2005 or later. The dependent variable takes a value of 1 if the default is direct and 0 otherwise. The coefficient on recourse is negative and statistically significant. Controlling for the above characteristics, measured at the sample means, recourse decreases the likelihood that the default is direct by 6% in the full sample. The effect of recourse is statistically significant only for loans with appraisal amounts at origination of $\$300,000$ to $\$750,000$. Unlike our finding for the effect of recourse on default, the effect is not statistically significant for loans on properties appraised at $\$750,000$ to \$1 million at origination although we have only 618 observations in this sample.

Borrowers with higher FICO scores who default are more likely to default directly. This effect is highly statistically significant for the full sample and every appraisal category; a higher FICO score is the most robust predictor of direct default. This is consistent with an analysis by Experian - Oliver Wyman (2009), which finds that prime borrowers are more likely to strategically default than non-prime borrowers. The effect is quantitatively important: a 100 basis point increase in the borrower's FICO score at origination makes it 20% more likely that any default that does occur will be direct. We also find that direct defaults are more frequent from 2005 onwards, and that borrowers who have more expensive properties, as measured by the real appraisal amount at origination, are more likely to default strategically.

6 Is Recourse Priced?

To the extent that borrowers in recourse states are less likely to default in response in negative equity, and are more likely to default in a lender-friendly way if they do default,

lenders are likely to face smaller losses from default in recourse states. Thus, one might expect to see lower interest rates in recourse states. To explore this question, we regress the contract rate at origination for all fixed rate mortgages in our sample on the recourse dummy variable, our main controls, and year of origination dummies. Column 1 of Table 13 presents the results of this regression for the sample of both purchase and non-purchase mortgages. The coefficient on recourse is positive and statistically significant, indicating that borrowers in recourse states in fact face higher, rather than lower, interest rates. We find the same result when we estimate the effect of recourse on loan pricing in the sample of only purchase mortgages (column 2) as well as in the sample of only non-purchase mortgages (column 3).

Since our earlier results indicate that recourse only has an effect on mortgages on more expensive properties, we estimate the relationship between recourse and interest rates on mortgages on properties of different appraised values at origination. Table 14 contains these results. Recourse continues to have a positive and statistically significant effect on the mortgage rate for properties appraised at $\$750,000$ to $\$1,000,000$. We found that recourse had a strong deterrent effect for mortgages on properties in this value range. In no appraisal category do we see evidence that borrowers in recourse states enjoy lower interest rates. We also find that rates on privately held mortgages are no lower in recourse states than rates on privately held mortgages in non-recourse states.

What could explain this perplexing finding? First, recall that we find no evidence that recourse states have lower default rates when we include recourse only in levels in our regression. Thus, it is perhaps not entirely surprising that our rate regression, which also includes recourse only in levels, does not show that recourse lowers the default rate. Lenders may also have attached a very low probability to the state of the world in which home prices fell enough that middle- and upper-income home owners, the types of households for which recourse deters default, default on their mortgages. However, the fact that the coefficient is positive and statistically significant suggests there may be important differences across states unrelated to recourse. For example, there may be differences in the amount of lender competition across states. Furthermore, our data do not include any information on origination points. Lenders may be pricing recourse using fees at origination rather than the contract rate. There may also be differences in lenders' expectations of future home price

appreciation.[13] All of these explanations are plausible; future work is needed to disentangle them.

7 Conclusions and Discussion

We empirically investigate the effect of recourse on default. We find that, in a sample of loans originated between August 1997 and December 2008, at the mean value of the default option at the time of default, the probability of default is 32% higher in non-recourse states than in recourse states. The deterrent effect on default is significant only for borrowers with appraised property values of $200,000 or more at origination. At the mean value of the default option at the time of default and for homes appraised at $300,000 to $500,000, borrowers in non-recourse states are 81% more likely to default than borrowers in recourse states. For homes appraised at $500,000 to $750,000, borrowers in non-recourse states are more than twice as likely to default as borrowers in recourse states. For homes appraised at $750,000 to $1 million, borrowers in non-recourse states are 60% more likely to default. We also find that recourse deters default on loans held privately; we cannot reject the hypothesis that recourse does not have an effect on loans held by the government sponsored enterprises. Finally, we find that allowing lenders recourse increases the likelihood that default occurs by a more lender-friendly method, such as a deed in lieu of foreclosure.

Our findings shed light on the ongoing discussions about the existence of strategic default. The result that recourse deters default indicates that at least some of the defaults in the data are strategic rather than involuntary (i.e., the borrower has no choice but to default because of liquidity constraints). Our results indicate that at least some borrowers choose not to default when the lender has recourse, indicating that they are capable of continuing to make payments on their mortgage.

Our results regarding the differential effect of recourse by appraisal amount of the mortgaged property indicate that at least some defaults on high- and moderately priced homes

[13] We explored some specifications for the interest rate in which we had measures of future expected home price appreciation. In no specification did we find that recourse lowered the mortgage interest rate. However, our measures of future expected home price appreciation were based on lagged home prices and likely were not close approximations of lenders' actual expectations.

are strategic. We cannot eliminate the possibility that some of the defaults on low-priced homes are strategic; the appraisal amount is a proxy for both the lender's amount of recourse and the borrower's financial means in general. Recourse may not significantly affect default on low-priced homes for one of two reasons. The first possibility is that most households with low-priced homes are liquidity constrained and thus default because of their inability to carry payments. Alternatively, for low-priced properties, the lender's recovery on a deficiency judgment may be low in practice both because of a low recovery rate and a relatively higher fixed cost.

The finding that recourse has a differential effect on the probability of default depending on the appraisal amount of the mortgaged property also suggests that the default decision depends on the borrower's income in recourse states. This effect works via the expected deficiency judgment, which allows the lender to claim a part of the borrower's assets. The fact that the default decision depends on income is relevant for policy discussions of the impact of default on welfare (see Hatchondo, Martinez, and Sanchez [2010]).

Table 1: State Foreclosure Laws

State	Judicial or Non-Judicial Foreclosure	Optimum timeline*	Recourse Classification	State	Judicial or Non-Judicial Foreclosure	Optimum timeline*	Recourse Classification
Alabama	NJ	49-74	Recourse	Nebraska	NJ	121	Recourse
Alaska	NJ	108-111	Non-Recourse	Nebraska	J	176	
Arizona	NJ	115	Non-Recourse	Nevada	Nj	116	Recourse
Arkansas	NJ	90	Recourse	New Hampshire	NJ	75	Recourse
California	NJ	120	Non-Recourse	New Jersey	J	295	Recourse
Colorado	NJ	173	Recourse	New Mexico	J	225	Recourse
Connecticut	J, strict	160	Recourse	New York (NYC)	J	445	Recourse
Connecticut	J, by decree of sale	235		New York (Outside NYC)	J	299	
DC	NJ	48	Recourse	New York (Outside NYC)	NJ	355	
Delaware	J	200-300	Recourse	North Carolina Purchase Mortgages	NJ	120	Non-Recourse
Florida	J	150	Recourse	North Carolina Other Mortgages	NJ	120	Recourse
Georgia	NJ	48	Recourse	North Dakota	J	150	Non-Recourse
Hawaii	NJ	195	Recourse	Ohio	J	217	Recourse
Hawaii	J	320		Oklahoma	NJ	201	Recourse
Idaho	NJ	150	Recourse	Oregon	NJ	160	Non-Recourse
Illinois	J	345	Recourse	Pennsylvania	J	300	Recourse
Indiana	J	266	Recourse	Rhode Island	NJ	74	Recourse
Iowa	J	180	Non-Recourse	South Carolina	J	180	Recourse
Kansas	J	230	Recourse	South Dakota	J	340	Recourse
Kentucky	J	198	Recourse	Tennessee	NJ	50-55	Recourse
Louisiana	J, executory process	209	Recourse	Texas	NJ	35-60	Recourse
Louisiana	J, non-executory	269		Texas	J	80-180	
Maine	J	270	Recourse	Utah	NJ	139	Recourse
Maryland	J	46	Recourse	Vermont	J	275	Recourse
Massachusetts	J	75	Recourse	Virginia	NJ	60	Recourse
Michigan	NJ	360**	Recourse	Washington	NJ	140-150	Non-Recourse
Minnesota	NJ	270-280***	Non-Recourse	West Virginia	NJ	120	Recourse
Missouri	NJ	61-65	Recourse	Wisconsin	J	315	Non-Recourse
Montana	NJ	163	Non-Recourse	Wyoming	NJ	180	Recourse
Mississippi	NJ	90	Recourse				

Notes: * These are optimum timelines from The National Mortgage Servicer's Reference Directory, 21st edition (2004). The optimum timelines assume no delays and are based on uncontested foreclosure actions. ** The non-judicial foreclosure optimally takes 60 days; however, after that the redemption period begins to run, typically for 6 months. Estimated time for completion for uncontested foreclosure without eviction action is 12 months. ***The sale in non-judicial foreclosure can generally be held within 90 days; however, there are substantial redemption rights in Minnesota. Thus, including the redemption period the optimum timeframe for non-judicial foreclosure is 270-280 days.

Table 2: Summary Statistics

	Mean	Std. Dev.	5th Percentile	95th Percentile	Mean Recourse Loans	Mean Non-Recourse Loans
Recourse	0.67	0.47	0	1	1	0

LTV 80 Dummy	0.14	0.35	0	1	0.14	0.14
Appraisal Amount (at Origination)	308,043	303,093	82,000	750,000	275,149	391,624
Number of Loans	2,922,196				1,924,773	997,423
Number of Defaults	43,353				27,927	15,426

Notes: Recourse is a dummy variable that takes a value of 1 if the property is in a recourse state, 0 otherwise; for North Carolina, recourse takes a value of 1 if the loan is not a purchase mortgage, 0 otherwise. The rate variables control for the difference between the current mortgage rate and the contract rate. Purpose Type Dummy takes a value of 1 if the loan is not a purchase mortgage, 0 otherwise. LTV80 Dummy takes a value of 1 if the loan-to-value at origination is 80%.

Notes: The dependent variable in the probit is a binary variable that takes a value of 1 if the loan defaults in that month, 0 otherwise. Default Option is the probability that the borrower has negative home equity. LTV80 takes a value of 1 if the loan has an LTV of exactly 80%, 0 otherwise. The rate variables control for the difference between the current mortgage rate and the contract rate. Purpose Type Dummy takes a value of 1 if the loan is not a purchase mortgage, 0 otherwise. Standard errors are in parentheses. The coefficients and standard errors for Fico Score at Origination show the effect of a 100 point increase in the FICO score. Standard errors are clustered by state. Coefficients in bold font are significant at the 5% level. % Defaults is the percentage of observations that are defaults.

Table 4: Estimated Default Probabilities in Recourse and Non-Recourse States

Recourse Def. Prob.	0.0558%	0.0189%	0.0191%	0.0257%
Ratio NR/R	144%	111%	113%	174%

Note: The benchmark specification is specification (2) from table 3. The probabilities are estimated at the modes for dummy variables and means for the variables other than the default option value and default option value squared. In column 1, we estimate the probabilities at the modes of dummy variables and the means of all variables at the time of default for defaulted loans. Ratio is the ratio of the probabilities in non-recourse and recourse states.

Notes: The dependent variable in the probit is a binary variable that takes a value of 1 if the loan defaults in that month, 0 otherwise. Default Option is the probability that the borrower has negative home equity. LTV80 takes a value of 1 if the loan has an LTV of exactly 80%, 0 otherwise. The rate variables control for the difference between the current mortgage rate and the contract rate. Purpose Type Dummy takes a value of 1 if the loan is not a purchase mortgage, 0 otherwise. Standard errors are in parentheses. The coefficients and standard errors for Fico Score at Origination show the effect of a 100 point increase in the FICO score. Standard errors are clustered by state. Coefficients in bold font are significant at the 5% level. % Defaults is the percentage of observations that are defaults.

Notes: The dependent variable in the probit (columns 1-3) is a binary variable that takes a value of 1 if the loan defaults in that month, 0 otherwise. Default Option is the probability that the borrower has negative home equity. LTV80 takes a value of 1 if the loan has an LTV of exactly 80%. The rate variables control for the difference between the current mortgage rate and the contract rate. Purpose Type Dummy takes a value of 1 if the loan is not a purchase mortgage, 0 otherwise. Standard errors are in parentheses. The coefficients and standard errors for Fico Score at Origination show the effect of a 100 point increase in the FICO score. Columns 4 and 5 present hazard ratios from the estimated proportional hazard semiparametric models; standard errors are clustered by loan. The results in column 4 are from hazard functions for grouped data estimated separately, treating the competing hazard as censored. The results in column 5 are from the joint estimation of competing hazard functions for grouped data; due to computational constraints, we reduce our sample to a random 40% sample of our sample in this specification. Standard errors are
clustered by state for the probit models. Coefficients in bold font are significant at the 5% level. % Defaults is the % of observations that are defaults.

Notes: The dependent variable in the probit is a binary variable that equals 1 if the loan defaults in that month, 0 otherwise. The benchmark specification is specification (3) from table 3 (recourse in interactions). Default Option is the probability that the borrower has negative home equity. LTV80 takes a value of 1 if the loan has an LTV of exactly 80%, 0 otherwise. The rate variables control for the difference between the current mortgage rate and the contract rate.The results for Fico Score at Origination show the effect of a 100 point increase. Purpose Type Dummy takes a value of 1 if the loan is not a purchase mortgage, 0 otherwise. % Defaults is the percentage of observations that are defaults. Standard errors (clustered by state) in parentheses. All regressions include a constant.

Notes: Dependent variable in the probit is a binary variable that equals 1 if the loan defaults in that month, 0 otherwise. The benchmark specification is specification (3) from table 3 (recourse in interactions). Default Option is the prob. that the borrower has negative home equity. LTV80=1 if the loan has an LTV of exactly 80%, 0 otherwise. Rate variables control for the difference between the current mortgage rate and the contract rate. The results for Fico Score show the effect of a 100 point increase. Purpose Type Dummy = 1 if the loan is not a purchase mortgage, 0 otherwise. % Defaults is the % of observations that are defaults. Standard errors (clustered by state) in parentheses. All regressions include a constant.

Table 9: Recourse, Expected LTVs, and the Probability of Default

Number of obs.	85,888,286	7,076,266	26,973,983	20,004,481	19,840,252	7,675,467	2,370,213	1,947,624

Notes: The dependent variable in the probit is a binary variable that equals 1 if the loan defaults in that month, 0 otherwise. The expected LTV is the current LTV (in %) computed using average state home prices. LTV80 takes a value of 1 if the loan has an LTV of exactly 80%, 0 otherwise. The rate variables control for the difference between the current mortgage rate and the contract rate.The results for Fico Score at Origination show the effect of a 100 point increase. Purpose Type Dummy takes a value of 1 if the loan is not a purchase mortgage, 0 otherwise. % Defaults is the percentage of observations that are defaults. Standard errors (clustered by state) in parentheses. Robustness results are available from the authors. Coefficients in bold font are significant at the 5% level.

Table 10: Increase in Expected LTV for Default in Recourse States Relative to Non-Recourse States

All	< $100,000	$100,000 to $200,000	$200,000 to $300,000	$300,000 to $500,000	$500,000 to $750,000	$750,000 to $1,000,000	> $1,000,000
8.6%	-3.8%	1.5%	10.7%	22.0%	24.0%	12.8%	2.8%

Notes: This table uses the coefficients from table 9 to compute the increase in the expected LTV in a recourse state relative to that in a non-recourse state. The interpretation is that borrowers in recourse states on average default at an expected LTV that is x% higher than the expected LTV at which a borrower would default at in a non-recourse state.

Number of obs.	43,353	43,353	43,353	43,252	43,353

Notes: The dependent variable in the probit is a binary variable that takes a value of 1 if default is by foreclosure, 0 otherwise. Default Option is the probability that the borrower has negative home equity. Recourse is a dummy variable that takes a value of 1 if the property is in a recourse state, 0 otherwise. The coefficients and standard errors for Fico Score at Origination show the effect of a 100 point increase. Foreclosure timing dummy is a dummy variable that takes a value of 1 if the uncontested foreclosure time is less than six months. Investor type 1 is a dummy variable that takes a value of 1 if the lender type is not "Private Portfolio" or "Private Securitized", 0 otherwise. Appraisal amount is the appraisal amount of the property at origination; coefficients and standard errors shown are for the effect of a $100,000 increase. The number of observations in column 4 differs from the number of observations in other columns because we exclude observations with investor type "Unknown" for these specifications. In all specifications standard errors are clustered by state. Coefficients in bold font are significant at the 5% level.

Table 12: Direct Defaults and Recourse

	All	< $100,000	$100,000 to $200,000	$200,000 to $300,000	$300,000 to $500,000	$500,000 to $750,000	$750,000 to $1,000,000	> $1,000,000

Number of obs.	32,172	5,559	9,347	5,988	7,227	3,042	618	391

Notes: The dependent variable in the probit is a binary variable that takes a value of 1 if the default is direct , 0 otherwise. A direct default refers to a default in which there is no evidence the borrower tried to resume payments prior to losing the home; see text for full details. Default Option is the probability that the borrower has negative equity. Recourse is a dummy variable that takes a value of 1 if the property is in a recourse state, 0 otherwise. The coefficients and standard errors for Fico Score at Origination show the effect of a 100 point increase. Foreclosure timing dummy is a dummy variable that takes a value of 1 if the uncontested foreclosure time is less than six months. Appraisal amount is the appraisal amount of the property at origination; coefficients and standard errors shown are for the effect of a $100,000 increase. Standard errors are clustered by state. Coefficients in bold font are significant at the 5% level. Robustness results available from the authors.

	(1.36)		
R-squared	56.41%	57.85%	60.69%
Number of obs.	2,254,676	781,814	1,472,862

Notes: The dependent variable is the current mortgage interest rate. LTV80 takes a value of 1 if the loan has an LTV of exactly 80%, 0 otherwise. Purpose Type Dummy takes a value of 1 if the loan is not a purchase mortgage, 0 otherwise. Standard errors clustered by state are in parentheses. The coefficients and standard errors for all variables except the loan amount are multiplied by 100; the coefficient and the standard error on the loan amount variable are multiplied by 1,000,000. Coefficients in bold font are significant at the 5% level. Additional controls include a full set of year of origination dummies.

Notes: The dependent variable is the current mortgage interest rate. LTV80 takes a value of 1 if the loan has an LTV of exactly 80%, 0 otherwise. Purpose Type Dummy takes a value of 1 if the loan is not a purchase mortgage, 0 otherwise. Standard errors clustered by state are in parentheses. The coefficients and standard errors for all variables except the loan amount are multiplied by 100; the coefficient and the standard error on the loan amount variable are multiplied by 1,000,000. Coefficients in bold font are significant at the 5% level. Additional controls include a full set of year of origination dummies.

A Foreclosure Laws State by State

Alabama: Lenders may foreclose through either a judicial or a non-judicial procedure. State law permits deficiency judgments without significant restrictions. We classify Alabama as a RECOURSE state. The borrower retains a right of redemption for one year after foreclosure. The relevant statutes are in section 35-10 of the Alabama Code.

Alaska: Lenders may foreclose through either a judicial or a non-judicial procedure. The usual financing instrument is a deed of trust and non-judicial foreclosure is the usual foreclosure process. State law permits deficiency judgments only if the lender pursues judicial foreclosure under the promissory note; no separate "deficiency judgment" is entered. The property sold at a judicial sale is subject to a right of redemption, and the redemption period is 12 months. As judicial foreclosure is substantially more time consuming and cumbersome, we classify Alaska as a NON-RECOURSE state. The relevant statutes are in Title 34, Ch. 20, Section 100 of the Alaska Statutes.

Arizona: Lenders may foreclose through either a judicial or a non-judicial procedure. The usual financing instrument is a deed of trust and non-judicial foreclosure is the usual foreclosure process. Deficiency judgments are not permitted if the property is residential and on 2.5 acres or less and its intended use was for a one-family dwelling or two-family dwelling. We classify Arizona as a NON-RECOURSE state. The relevant statute is Article 33 of the Arizona State Code.

Arkansas: Lenders may foreclose through either a judicial or a non-judicial procedure. Lenders usually foreclose on a deed of trust through a non-judicial procedure. State law permits deficiency judgments with the restriction that borrowers must receive credit for the greater of the foreclosure sales price or the fair market value of the property. We classify Arkansas as a RECOURSE state. The relevant statutes are in sections 18-50-212 and 18-50-216 of the Arkansas Code.

California: Lenders may foreclose through either a judicial or a non-judicial procedure. Non-judicial foreclosure is the usual foreclosure process. The borrower has five days to reinstate in a non-judicial foreclosure process. State law prohibits deficiency judgments on

purchase mortgages. On other residential mortgages, state law permits deficiency judgments only if the lender pursues the more expensive and time-consuming judicial foreclosure process rather than the non-judicial foreclosure process. The lender may only file for a payment of the difference between the debt owed and the fair market value of the property. A deficiency suit also gives the borrower a right to redemption. We classify California as a NON-RECOURSE state. The relevant statutes are in sections 2920-2944.5 of the California Code.

Colorado: Lenders may foreclose through either a judicial or a non-judicial procedure. Non-judicial foreclosure is the norm. State law permits deficiency judgments. However, judges require lenders to bid fair market value on the property in the event that total debt owed exceeds the property value less reasonable expenses; if the borrower can show that lenders bid less than fair market value, the borrower can avoid a deficiency judgment. After the sale, there is a redemption period of 75 days. There are no unreasonably burdensome statutory limitations on either filing or collecting on a deficiency or collection. We classify Colorado as a RECOURSE state. The relevant statutes are Title 38, Articles 37-39 of the Colorado Revised Statutes.

Connecticut: Lenders may foreclose only through one of two judicial procedures. The two procedures are a strict foreclosure and a decree of sale foreclosure. State law permits deficiency judgments under both procedures; however, if the lender pursues decree of sale foreclosure the lender must first credit the borrower with one-half the difference between the debt and the appraised value if the property is sold pursuant to a court-order and the property sells for less than the appraised value. In strict foreclosure, the judge determines the fair market value of the property for which the borrower receives credit; a motion for deficiency judgment must be filed within 29 days of title vesting. There is no statutory deadline to file the motion for deficiency judgment after foreclosure-by-sale. We classify Connecticut as a RECOURSE state. The relevant statutes are sections 49-14 and 49-28 of the General Statutes of Connecticut.

Delaware: Lenders may foreclose only through a judicial procedure. State law permits deficiency judgments without significant restrictions. We classify Delaware as a RECOURSE state. The relevant statute is Title 10, Ch. 49:XI of the Delaware Code.

District of Columbia: Lenders may only foreclose through a non-judicial procedure. At any time within thirty days after the time limit for redemption has expired, any party to a mortgage foreclosure may file a motion seeking a deficiency judgment. We classify the District of Columbia as a RECOURSE district. The relevant statute is Title 42, Ch. 8 of the District of Columbia Code.

Florida: Lenders may foreclose only through judicial foreclosure. State law permits deficiency judgments subject to the borrower receiving credit for the greater of fair market value of the property or the foreclosure sale price. A deficiency judgment can be pursued against the original makers of a note even if they were not a party to the foreclosure action. However, Florida has an extremely generous homestead exemption such that if the property is an investment property rather than a primary residence, the borrower can partially shield his or her assets from collection on the deficiency. We classify Florida as a RECOURSE state. The relevant statutes are Title 40, Ch. 702 of the Florida Statutes.

Georgia: Lenders may foreclose through either a judicial or a non-judicial procedure. Non-judicial foreclosure is the usual process. A prerequisite to a deficiency judgment is that the court has confirmed and approved the sale, which in turn requires that the sale price was equal to at least the fair market value of the property. The lender must receive such confirmation and approval within 30 days of the foreclosure sale. There is no right of redemption. We classify Georgia as a RECOURSE state. The relevant statutes are in Title 44, Ch. 14 of the Official Code of Georgia.

Hawaii: Lenders may foreclose through either a judicial or a non-judicial procedure. A judicial foreclosure takes 320 days; non-judicial takes 195 days if uncontested. State law permits deficiency judgments if the lender pursues judicial foreclosure. The deficiency judgment process, if not contested, is fairly inexpensive. We classify Hawaii as a RECOURSE state. The relevant statutes are Ch. 667-5 and Ch. 667-38 of the Hawaii Revised Statutes.

Idaho: Lenders may foreclose through either a judicial or a non-judicial procedure, although judicial foreclosure is exceptionally rare. State law permits a deficiency judgment provided one is filed within 90 days of the foreclosure sale. The deficiency is limited to the

difference between the balance owed and the fair market value of the property. The deficiency judgment process is onerous in practice since the lender must prove fair market value and the borrower can contest the fair market value of the property. We classify Idaho as a RECOURSE state. The relevant statutes are in Idaho Statutes, Title 45, Ch. 15, Section 45.12.

Illinois: Lenders may foreclose only through judicial foreclosure. State law permits deficiency judgments provided the borrower is personally served with the deficiency suit. Furthermore, a judge must confirm the sale and, according to Ch. 735, Article XV, Section 15-1508, the judge may opt to not confirm the sale on the grounds that "justice was not otherwise done." In practice, this means that is at the discretion of the judge whether to grant a deficiency judgment and judges rarely grant deficiency judgments on residential property. We classify Illinois as a RECOURSE state because the possibility of personal recourse may be sufficient to deter some strategic defaulters even if deficiency judgments are rarely granted. The relevant statutes are in Ch. 735, Article XV of the Illinois Compiled Statutes.

Indiana: Lenders may foreclose only through judicial foreclosure, which optimally takes 266 days if uncontested. State law permits deficiency judgments on residential properties without significant restrictions. The borrower must be served in person, which is not a significant restriction in practice. We classify Indiana as a RECOURSE state. The relevant statutes are in Article 29, Ch. 7 of the Indiana State code.

Iowa: Lenders may foreclose only through judicial foreclosure. State law permits deficiency judgments on nonagricultural residential properties. However, seeking a deficiency judgment significantly delays the foreclosure process. Furthermore, there is a two-year statute of limitations on collecting on the deficiency judgment and generous limits on garnishment of wages. The law makes it much faster to foreclosure on property if the lender waives the right to a deficiency judgment. Because deficiencies are hard to collect in Iowa, lenders may even compensate the borrower who agrees to vacate the property fast by paying the first month of rent on new housing. We classify Iowa as a NON-RECOURSE state. The relevant statute is Ch. 654.6 of the Iowa code.

Kansas: Lenders may foreclose only through judicial foreclosure. Following a foreclosure sale, a deficiency judgment is automatically entered if the sale proceeds less expenses are not sufficient to cover the debt owed. The borrower may contest the deficiency if the foreclosure sales price was less than the fair market value of the property. Kansas is unusual as redemption rights can be sold to third parties such that if the lender bids substantially less for the property than its fair market value, the holder of the redemption rights may obtain the property at significantly below market value. Further, second lien holders lose the right to a deficiency if they do not ask for a foreclosure themselves. We classify Kansas as a RECOURSE state. The relevant statute is Ch. 60, 2417 of the Kansas Statutes.

Kentucky: Lenders may foreclose only through judicial foreclosure. Following a foreclosure sale, a deficiency judgment is automatically entered if the sale proceeds less expenses are not sufficient to cover the debt owed. There are no significant restrictions. We classify Kentucky as a RECOURSE state. The relevant statutes are in Ch. 426 of the Kentucky Revised Statutes.

Louisiana: Lenders may foreclose only through judicial foreclosure. State law permits deficiency judgments on residential properties without significant restrictions. We classify Louisiana as a RECOURSE state. The relevant statutes are in Title 10:9-629 of the Louisiana Code.

Maine: Lenders may foreclose only through judicial foreclosure. State law permits deficiency judgments on residential properties provided the lender credits the borrower's account for fair market value of the property. We classify Maine as a RECOURSE state. The relevant statutes are in Title 14, Part 4, Ch. 403 of the Revised Maine Statutes.

Maryland: Lenders may foreclose through either a judicial or a non-judicial procedure. State law permits deficiency judgments on residential properties without significant restrictions. We classify Maryland as a RECOURSE state. The relevant statutes are in the Maryland Rules, Title 14, Ch. 200.

Massachusetts: Lenders may foreclose through either a judicial or a non-judicial procedure. State law permits a deficiency judgment provided that the lender gives the borrower

notice in writing prior to the foreclosure sale that he or she intends to pursue a deficiency. We classify Massachusetts as a RECOURSE state. The relevant statutes are in Ch. 244 of the General Laws of Massachusetts.

Michigan: Lenders may foreclose through either a judicial or a non-judicial procedure. There is typically a six-month redemption period after the completion of a non-judicial foreclosure. State law permits a deficiency judgment without significant restrictions in the case of judicial foreclosure; in the case of non-judicial foreclosure, the borrower can contest the deficiency if the property sold for substantially less than the fair market value. We classify Michigan as a RECOURSE state. The relevant statutes are in the Michigan Compiled Laws, Ch. 451; EPIC Act 236, Sections 600 and 700.

Minnesota: Lenders may foreclose through either a judicial or a non-judicial procedure, although in the vast majority of cases, lenders foreclose through a non-judicial process. There are substantial redemption rights in Minnesota. In particular, the mortgagor is entitled to a 6- or 12-month period after the foreclosure sale. The mortgagor is entitled to possession of the property and the lender has limited right to enter the property. The redemption period can be shortened to 6 months if certain conditions are met. A separate court procedure is required to shorten the redemption period to 5 weeks if the residential property is deemed "abandoned" and of less than 5 units and is on less than 10 acres. Thus, including the redemption period the optimum timeframe for non-judicial foreclosure is 270-280 days. In the event the lender forecloses by advertisement, state law prohibits deficiency judgments. In judicial foreclosure, the lender may obtain a deficiency judgment subject to the borrower receiving credit for the fair market value of the property. The fair market value of the property is determined by a jury. Because judicial foreclosure is substantially more onerous than the non-judicial procedure, lenders pursue non-judicial foreclosure in the vast majority of cases. We classify Minnesota as a NON-RECOURSE state. The relevant statutes are in 580 and 582 of the 2008 Minnesota Statutes and, particularly, 582.2, Subdivision 2.

Mississippi: Lenders may foreclose on deeds of trusts or mortgages in default using either a judicial or non-judicial foreclosure process. State law permits a deficiency judgment provided the lender files for one within one year of the foreclosure sale date. If a mortgagee participates

in foreclosure sale auction, his bid must pass a judicial standard of reasonableness. We classify Mississippi as a RECOURSE state. The relevant statutes are in Section 89-1-305 of the Mississippi State Code.

Missouri: Lenders may foreclose through either a judicial or a non-judicial procedure. The state has a statutory right of redemption, but a burden on the borrower is prohibitively heavy and this right can be rarely exercised. In the case of a non-judicial foreclosure sale, a separate court action must be filed to obtain a deficiency judgment, but there are no other significant restrictions on obtaining a deficiency judgment. We classify Missouri as a RECOURSE state. The relevant statutes are in the Missouri Revised Statutes, Ch. 141 Sections 400-590.

Montana: Lenders may foreclose through either a judicial or a non-judicial procedure. Deficiency judgments are prohibited on purchase mortgages by title 71, chapter 1-232 of the Montana Code Annotated. Deficiency judgments are permitted on other types of residential mortgages only if the lender pursues judicial foreclosure; however, judicial foreclosure is often impractical because the grantor is entitled to a one-year right of redemption. The non-judicial foreclosure process is also substantially less complicated and costly. We classify Montana as a NON-RECOURSE state. The relevant statutes are in Title 71, Ch. 1 of the Montana Code Annotated.

Nebraska: Lenders may foreclose through either a judicial or a non-judicial procedure. Lenders may obtain a deficiency judgment; however, the borrower must receive credit for the fair market value of the property and the deficiency must be filed for within 90 days of the foreclosure sale by non-judicial foreclosure and within 5 years in case of judicial foreclosure. We classify Nebraska as a RECOURSE state. The relevant statutes are in the Nebraska Revised Statutes Ch. 76-1013.

Nevada: Lenders may foreclose through either a judicial or a non-judicial procedure. Usually properties are foreclosed through a non-judicial procedure. A deficiency judgment can be obtained; however, the borrower must receive credit for the greater of the fair market value of the property, as determined through a hearing, or the foreclosure sale price. The

lender must file for a deficiency judgment with 90 days of the foreclosure sale. We classify Nevada as a RECOURSE state. The relevant statutes are in the Nevada Revised Statutes, Chs. 40, 106, and 107.

New Hampshire: Lenders may foreclose through either a judicial or a non-judicial procedure. Almost all properties are foreclosed non-judicially. There are no significant restrictions on deficiency judgments. We classify New Hampshire as a RECOURSE state. The relevant statutes are in Title 38, Ch. 479 of the New Hampshire Revised Statutes.

New Jersey: Lenders foreclose through a judicial process. State law permits deficiency judgments but the borrower must be given credit for the fair market value of the property and must be brought within 3 months of the foreclosure sale. The pursuit of a deficiency judgment extends the redemption period from 10 days to 6 months. We classify New Jersey as a RECOURSE state. The relevant statutes are in the New Jersey Permanent Statutes Title 2A, Section 50.

New Mexico: Lenders foreclose on residential properties through a judicial process. Deficiency judgments on mortgages and deeds of trust other than those used to finance low-income housing can be obtained and there are no significant restrictions. We classify New Mexico as a RECOURSE state. The relevant statutes are in Ch. 48, Articles 48-7-1 to 48-7-24 and Articles 48-10-1 to 48-10-21 of the New Mexico Statutes Annotated.

New York: Lenders may foreclose through either a judicial or a non-judicial procedure, although non-judicial foreclosure is exceptionally rare. State law permits a deficiency judgment provided that the lender submits a request for a deficiency judgment within 90 days of filing the foreclosure suit. However, the borrower receives credit for the greater of the foreclosure sale price or the fair market value of the property. The judge usually sides with the borrower regarding the fair market value of the property. A typical deficiency judgment is relatively expensive. We classify New York as a RECOURSE state. The relevant statutes are in Article 13 of the New York State Consolidated Laws.

North Carolina: Lenders may foreclose through either a judicial or a non-judicial process. Ch. 45, Article 2B, Section 21.38 of the North Carolina General Statutes prohibits defi-

ciency judgments on purchase mortgages. We classify purchase mortgages in North Carolina as NON-RECOURSE. Deficiency judgments are permitted on other types of residential mortgages but the borrower has the right to contest the deficiency judgment such that he or she receives credit for the fair market value of the property. The deficiency judgment must be filed within one year. North Carolina law does not permit garnishment of wages to collect debt. We classify non-purchase mortgages in North Carolina as RECOURSE. The relevant statutes are Sections 21.36 and 21.38 of Article 2B in Ch. 45 of the North Carolina General Statutes.

North Dakota: Lenders foreclose through a judicial process. Ch. 32-19-01 of the North Dakota Century Code prohibits deficiency judgments on residential properties. This provision applies to residential property with four or fewer units on up to 40 contiguous acres if at least one unit is owner-occupied. We classify North Dakota as a NON-RECOURSE state.

Ohio: Lenders may foreclose only through judicial foreclosure. If the debt is greater than the foreclosure sales price plus reasonable expenses, a deficiency judgment is automatic. However, lenders have only two years to collect on the deficiency. We classify Ohio as a RECOURSE state. The relevant statutes are in the Ohio Revised Code, Section 2329.08.

Oklahoma: Lenders may foreclose through either judicial or non-judicial foreclosure. The optimum timeframe for non-judicial foreclosure is 201 days. Lenders may only receive a deficiency judgment if they pursue non-judicial foreclosure and the borrower must receive credit for the greater of the fair market value or the foreclosure sale price. The lender must file for a deficiency judgment within 90 days of the foreclosure sale. We classify Oklahoma as a RECOURSE state. The relevant statute is Title 12, Ch. 12, Section 686 of the Oklahoma Statutes Citationized.

Oregon: Lenders may foreclose through either a judicial or a non-judicial procedure. Lenders can generally not obtain a deficiency judgment on a residential property. We classify Oregon as a NON-RECOURSE state.

Pennsylvania: Lenders foreclose through a judicial procedure. Pennsylvania Law permits the lender to file for a deficiency judgment through a separate suit from the foreclosure but

the borrower must receive credit for the fair market value of the property. The deficiency suit must be brought within six months of the foreclosure sale. We classify Pennsylvania as a RECOURSE state. The relevant statute is the Pennsylvania Deficiency Judgment Act, Ch. 81 Section 8103 of the Pennsylvania Consolidated Statutes.

Rhode Island: Lenders may foreclose through either a judicial or a non-judicial procedure. Deficiency judgments can be obtained and there are no significant restrictions. We classify Rhode Island as a RECOURSE state. The relevant statutes are in Ch. 34-27 of the Rhode Island General Laws.

South Carolina: Lenders foreclose through a judicial procedure. State law permits deficiency judgments subject to the restriction that the borrower receive may present a motion to receive credit for the fair market value of the property. In such a circumstance, the borrower, judge, and lender all hire appraisers to determine the fair market value of the property. We classify South Carolina as a RECOURSE state. The relevant statutes are in Title 29, Ch. 3, Article 7 of the South Carolina Code of Laws.

South Dakota: Lenders may foreclose through either a judicial or a non-judicial procedure. State law permits deficiency judgments provided the borrower is credited for the fair market value of the property. We classify South Dakota as a RECOURSE state. The relevant statutes are in Ch. 21-47 of the South Dakota Codified Laws.

Tennessee: Lenders may foreclose through either a judicial or a non-judicial procedure although lenders seldom use the judicial foreclosure process. State law permits deficiency judgments without significant restrictions. We classify Tennessee as a RECOURSE state. The relevant statutes for non-judicial foreclosure are Title 21, Ch. 1, Section 803 of the Tennessee Code.

Texas: Lenders may foreclose through either a judicial or a non-judicial procedure. The lender must foreclose on a home equity loan through a judicial foreclosure process, however. State law permits deficiency judgments subject to the borrower receiving credit for the fair market value of the property. However, Texas has a nearly unlimited homestead exemption such that lenders have less recourse on mortgages backed by investment properties if the

borrower's primary residence is also in Texas. We classify Texas as a RECOURSE state. The relevant statutes are in Title 5, Section 51 of Texas Statutes.

Utah: Lenders may foreclose through either a judicial or a non-judicial procedure. State law permits deficiency judgments without significant restrictions. We classify Utah as a RECOURSE state. The relevant statutes are in Title 38, Ch.1-16 and Title 57, Ch. 1 of the Utah Code.

Vermont: Lenders may foreclose through either a judicial or, if the mortgage contains a power of sale clause, a non-judicial procedure. The norm, however, is judicial foreclosure. State law permits deficiency judgments with no significant restrictions. We classify Vermont as a RECOURSE state. The relevant Vermont Statutes are in Title 12, Ch. 163.

Virginia: Lenders may foreclose through either a judicial or non-judicial process. State law permits deficiency judgments with no significant restrictions. We classify Virginia as a RECOURSE state. The relevant statutes are in Title 8.9A Part 6 and Title 55, Ch. 4 of the Code of Virginia.

Washington: Lenders may foreclose through either a judicial or non-judicial process. If the lender wishes to pursue a deficiency judgment, however, it must pursue judicial foreclosure and pursuit of a deficiency judgment triggers a 12-month right of redemption. Furthermore, the judicial foreclosure process is substantially more time-consuming than the non-judicial process. Deficiency judgments can also not be obtained if the property has been abandoned for 6 months or more which we view as one way a strategic defaulter could evade a deficiency judgment relatively easily. We classify Washington as a NON-RECOURSE state. The relevant statutes are in Title 61, Ch. 61-12 of the Revised Code of Washington.

West Virginia: Lenders may foreclose through either a judicial or non-judicial process. West Virginia permits deficiency judgments without significant restrictions. We classify West Virginia as a RECOURSE state. The relevant statutes are in Articles 1 and 16 of Ch. 38 of the West Virginia Code.

Wisconsin: Lenders foreclose through a non-judicial process. A deficiency judgment must be filed at the time the foreclosure action starts. A waiver of a deficiency judgment may

reduce a redemption period of 12 months to 6 months, and a redemption period of 6 months to 3 months. The redemption period depends on a number of characteristics including parcel size. We classify Wisconsin as a NON-RECOURSE state. The relevant statutes can be found in Wisconsin Statutes and Annotations, Ch. 846.

Wyoming: Lenders may foreclose through either a judicial or non-judicial process. The lender generally bids the lesser of the debt owed or the fair market value of the property at a foreclosure sale. State law permits deficiency judgments without significant restrictions. We classify Wyoming as a RECOURSE state. The relevant statutes are in Title 34, Ch. 4 of the Wyoming Statutes.

B Data Description

B.1 Sample Restrictions

We restrict our analysis to mortgages with constant principal and interest, ARMs, or Graduated Payment Mortgages (GPM) (variable INT_TYPE takes values 1, 2, 5, respectively). Also, we restrict the analysis to mortgages taken out for purchase or refinance (PURPOSE_TYPE_MCDASH variable takes values 1 = Purchase, 2 = Refinance (Cash out), 3 = Refinance (No cash out), 5 = Refinance (Unknown cash)). We drop mortgages for home improvement, debt consolidation, education, medical, or other. The analysis is limited to first mortgages (Variable MORT_TYPE takes values 1 = First mortgage, or 4 = First mortgage, grade "B" or "C"). We restrict the sample to single-family residences, townhouse, or condos (PROP_TYPE=1 or C).

B.2 Variable Definitions

B.2.1 Definition of Default

We consider the loan as defaulted if the loan is terminated in one of the following ways: by REO sale, by short sale, by payoff out of foreclosure, by payoff out of bankruptcy or serious delinquency, or by liquidation to termination. We do not count terminations by

voluntary payoff or by a loan transfer from a servicer as defaults. The default month is determined as the first month the defaulted loan is reported as being in foreclosure, in REO proceedings, or under liquidation, whichever comes first (MBA_STAT variables takes values F, R, L, respectively). In addition, if the loan is terminated by default without loan status reported as any of the three mentioned above, the default month is the month when the loan is reported as paid off. Finally, if TERMINATION_TYPE=8, we count the loan as defaulted since the FORECLOSURE_TYPE for these variables is non-zero, indicating that there was a foreclosure although less than 0.1% of loans are terminated in this fashion.

B.2.2 Default Type

If a loan goes from being in foreclosure to being an REO loan, we treat it as a foreclosure. That is, we define a foreclosure as any loan for which MBA_STAT=F prior to it being any other MBA_STAT.

B.2.3 Default Option

For the current principal balance amount, we use variable PRIN_BAL_AMT (the balance the borrower owns on the loan); for the cost of a purchase we use variable ORIG_AMT (original loan amount). Loans for which the principal balance amount at the time of default (which is described bellow) is zero or missing and cannot be imputed from up to two previous months are dropped from the analysis. To calculate k_i we use the loan closing date (CLOSE_DT; as is used by McDash).

The OFHEO provides a quarterly (not seasonally adjusted) measure of the House Price Index by state (http://www.ofheo.gov/hpi_download.aspx). We use the all transactions index. The OFHEO provides A and B in quarters and so we convert months since origination into quarters since origination. We also construct monthly values of $HPI_{i,t}$ by linearly interpolating from the quarterly values, attributing the quarterly value to the second month of the quarter.

B.2.4 Prepay Option Variables

The ongoing contract rate on the mortgage is contained in variable CUR_INT_RATE. The market mortgage rate is a contract rate on the composite of all conventional mortgage loans (fixed and adjustable rate) from the Finance Board's Monthly Survey of Rates and Terms on Conventional Single-Family Nonfarm Mortgage Loans. The survey collects information on fully amortized conventional mortgage loans used to purchase single-family non-farm homes; mortgage loans insured by the Federal Housing Administration or guaranteed by the Veterans Administration are excluded. Loans used to refinance houses and non-amortized and balloon loans are also excluded. The data are available in Table 17, http://www.fhfb.gov/Default.aspx?Page=8&Top=4.

B.2.5 Trigger Events

State divorce rates are available on an annual basis for most years in our sample from the Division of Vital Statistics, National Center for Health Statistics, CDC. The data are available at
http://www.cdc.gov/nchs/data/nvss/Divorce%20Rates%2090%2095%20and%2099-07.pdf. We interpolate the values for 1997 and 1998 from the 1995 and 1999 values and use the 2007 value for 2008.

B.2.6 Loan Level Characteristics

- ln loan age in months from the closing date to the contemporaneous month
- LTV at origination
- an indicator variable if the loan is interest only at origination (IO_FLAG)
- an indicator variable if the loan is an option ARM (INT_TYPE)
- an indicator variable if the loan is a jumbo (JUMBO_FLG)
- an indicator variable if the loan is a refinance mortgage (PURPOSE_TYPE_MCDASH)

- the borrower's FICO score at origination (FICO_ORIG - original FICO score, available from 8/1997)
